2011 Pelagic Plan Team Report for Guam

Introduction and Summary

Pelagic fishing vessels based on Guam are classified into two general groups: distant-water purse seiners and longliners that fish outside Guam's economic exclusive zone (EEZ) and transship through the island, and small, primarily recreational, trolling boats that are either towed to boat launch sites or berthed in marinas and fish only within local waters, either within Guam's EEZ or on some occasions in the adjacent EEZ of the Northern Mariana Islands. This annual report covers primarily the local, Guam-based, small-boat pelagic fishery.

The estimated annual pelagic landings have varied widely, ranging between 322,000 and 937,000 pounds in the 30-year time series. The average total catch has shown a slowly increasing trend over the time period. The 2011 total pelagic landings were approximately 588,415 pounds, a decrease of 19% compared with 2010. Landings consisted primarily of five major species: mahimahi (Coryphaena hippurus), wahoo (Acanthocybium solandri), bonita or skipjack tuna (Katsuwonus pelamis), yellowfin tuna (Thunnus albacares), and Pacific blue marlin (Makaira mazara). Other minor species caught include rainbow runner (Elagatis bipinnulatus), kawakawa dogtooth tuna (Gymnosarda unicolor), double-lined (Euthynnus affinis), (Grammatorcynus bilineatus), and oilfish (Ruvettus pretiosus). Sailfish and sharks were also caught during 2011. However, these species were not encountered during offshore creel surveys and was not available for expansion for this year's report. While sailfish is kept, sharks are often discarded as bycatch. In addition to the above pelagic species, approximately half a dozen other species were landed incidentally this year.

The number of boats involved in Guam's pelagic or open ocean fishery gradually increased from 193 in 1983 to 469 in 1998. This number decreased until 2001, but has generally been increasing since that year. There were 454 boats involved in Guam's pelagic fishery in 2011, an increase of 5% from 2010. A majority of the fishing boats are less than 10 meters (33 feet) in length and are usually owner-operated by fishermen who earn a living outside of fishing. Most fishermen sell a portion of their catch at one time or another and it is difficult to make a distinction between recreational, subsistence, and commercial fishers. A small, but significant, segment of the pelagic group is made up of marina-berthed charter boats that are operated primarily by full-time captains and crews. Data and graphs for non-charters, charters, and bycatch are represented in this report.

There are general wide year-to-year fluctuations in the estimated landings of the five major pelagic species. Catch amounts for the five common species showed mixed changes from 2010 levels. 2011 mahimahi catch decreased more than 67% from 2010, wahoo catch totals decreased 16.2% from 2010, bonita increased by 3% from 2010, Pacific blue marlin catch decreased 41% from 2010, and yellowfin tuna increased 234% from 2010.

Aggregate landings of all pelagics, tuna, and non-tuna Pelagic Management Unit Species (PMUS) decreased in 2011 from 2010 levels. Landings of all pelagics decreased 19%, with tuna PMUS increasing 18% and non-tuna PMUS decreasing more than 58%. The number of trolling boats increased by 5%, the number of trolling trips decreased by 23.8% and hours spent trolling decreased by 16%. Weather on Guam was poor for much of 2010, with many days of wind and

rain. There was a higher than average number of small craft advisory days in 2010, which would limit the number of trips taken as well. Trolling catch rates (pounds per hour fished) showed a slight decrease compared with 2009. Total CPUE was down 1.5%, with yellow fin tuna showing the greatest increase. Bonita CPUE also increased, while marlin, and mahi mahi showed decreases. Wahoo CPUE was virtually unchanged from 2009.

Commercial landing data for 2011 shows a decrease from 2010 levels. Commercial landings and revenues decreased in 2011, with total adjusted revenues decreasing 37%. The adjusted average price for all pelagics decreased 4.7%, with tuna PMUS prices decreasing 2%, and non-tuna PMUS decreasing 5%. Adjusted revenue per trolling trip decreased 7.1% for all pelagics, increased 98.2% for tuna PMUS, and decreased 23.3% for non-tuna PMUS. Commercial landings have shown a decreasing trend over the past ten years. While the adjusted average price of pelagic species decreased last year, the number of boats in the fishery increased. A majority of troll fishermen do not rely on the catch or selling of fish as their primary source of income. Previously, Guam law required the government of Guam to provide locally caught fish to food services in government agencies, such as Department of Education and Department of Corrections. In 2002, the government of Guam began implementing cost-saving measures, including privatization of food services. The requirement that locally fish be used for food services, while still a part of private contracts, is not being enforced. This has allowed private contractors to import cheaper foreign fish, and reduced the sales of vendors selling locally caught fish. This represented a substantial portion of sales of locally caught pelagic fish. The decrease in commercial sales seen following 2002 may be, in part, due to this change.

In October, 2005, one 35 foot boat began short lining for sharks at the southern banks, with the expectation to sell shark meat to Mexico. After this venture failed, the vessel tried vertical long lining, short lining, and deep bottom fishing, all without commercial success. The fisherman has since switched his operation to shallow bottom fishing at offshore banks.

In early 2010, the U.S. military began exercises in an area south and southeast of Guam designated W-517. W-517 is a special use airspace (SUA) (approximately 14,000 nm2) that overlays deep open ocean approximately 50 miles south-southwest of Guam. Exercises in W-517 generally involve live fire and/or pyrotechnics When W-517 is in use, a notice to mariners (NTM) is issued, and vessels attempting to use the area are advised to be cautious of objects in the water and other small vessels. This discourages access to virtually all banks south of Guam, including Galvez, Santa Rosa, White Tuna, and other popular fishing areas. From 1982-2009, DAWR surveys recorded more than 2020 trolling and bottom fishing trips to these southern banks, an average of more than 72 trips per year. During 2011, 59 NTM comprising a total of 101 days (27.6% of all days) were issued for area W-517. This makes access to these banks less attractive fishing areas for more than 1/4 of the year. Additionally, the military occasionally holds exercises that do not involve live fire, but still restrict access to the area. As no notice is given for these events, there is not a reliable way to track how frequently this occurs

The shortage of staff biologists has been significant in the past several years. DAWR staff biologists continue to oversee several projects simultaneously, while providing on-going training to ensure the high quality of data being collected by all staff. All fisheries staff are trained to identify the most commonly caught fish to the species level. New staff are mentored by biologists and senior technicians in the field before conducting creel surveys on their own.

The makeshift ramp at Ylig Bay was eliminated in 2010. Widening of the main road on the south east coast of Guam will cause removal of the ramp. In December, 2006, a new launch ramp and facility was opened in Acfayan Bay, located in the village on Inarajan on the southeast coast of Guam. Monitoring of this ramp for pelagic fishing activity began at the start of 2007. In early 2007, this facility was damaged by heavy surf, and has yet to be repaired. Monitoring of this ramp is currently on hold until the ramp is repaired. The current financial situation in Gov Guam makes it unlikely this ramp will be repaired in the near future. With the loss of the Ylig ramp and the destruction of the ramp in Acfayan bay, there will be no boat launching facilities on the east side of Guam.

No FADs were deployed in 2011. Issues with procurement delayed awarding of a FAD deployment contract. DAWR has two more systems, and is awaiting the awarding of the deployment contract to deploy the remaining 2. This should bring the number of FADS on station to 9, of the fourteen considered to be a full complement.

For more information, the WESPAC website is www.wpcouncil.org.

Recommendations

2010 Recommendations

- 1. The PPT recommends that the Council discuss with the military methods of documenting and surveying fishing activity taking place on military bases. The military provides vessels for recreational use by military personnel, to include fishing. This fishery is currently not documented by DAWR. DAWR personnel have had difficulty with access to military bases to document this fishing activity, while other civilian contractors and personnel are able to enter and exit military property much more freely. Ease of access to military property and personnel by DAWR staff seems to vary from command to command. A written document defining fisheries survey protocols, necessity, and DAWR access would be beneficial addressing this gap in fisheries data.
- 2. The PPT recommends that the Council work with the military to coordinate with Guam natural resource agencies and local fishermen groups to allow better access to areas restricted due to increased military activity and exercises. This includes, but is not limited to, area W-517.
- 3. The PPT encourages DAWR and WPacFIN to conduct additional outreach with commercial vendors to increase participation in the commercial receipts program. A changing demographic of fishers, who are selling to novel vendors that are not being captured by the current commercial receipts program, is resulting in an underreporting of commercial sales on Guam. Similar problems are also being experienced in Saipan. Distrust of agencies and the use of commercial receipts data seems to be a common reason for not participating in the program.

Figure 1a. Guam Annual Estimated Total Landings: All Pelagics, Tuna PMUS, and Non-Tuna PMUS

Interpretation: The estimated total pelagic, tuna, and non-tuna PMUS have exhibited a cyclic trend, with a peak year followed by one or two down years. Total pelagic catch peaked in 1996, and had been decreasing until 2005. Since 2005, total has generally been increasing. Factors relating to this cycle may have to do with the biology of the fish or be weather related. There is also evidence from the fishermen and historic creel survey data that some pelagic fish species are not caught consistently year round around Guam.

Total pelagic and non-tuna PMUS decreased 19% and 58% respectively, compared with 2010, while tuna landings increased 18%. Non-tuna PMUS catch was well below the 30 year average, while the tuna PMUS catch was well above the 30 year average, and was the highest total on record. Total catch was slightly below the 30 year average. Generally, skipjack tuna are consistently caught year round, with the other major pelagic species being more seasonal. There is now a small fleet of vessels targeting skipjack tuna. These vessels fish almost every day, which is contributing to the high levels of tuna catch.

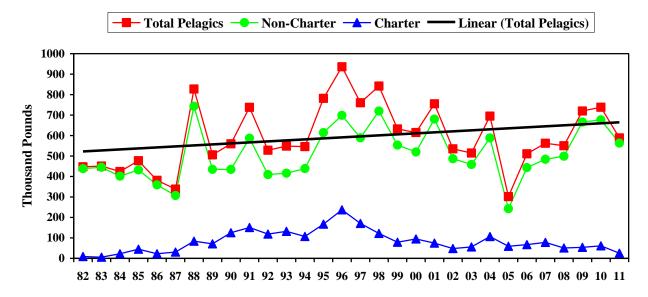

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel survey.

Calculation: A 365-day (366 days during leap years) quarterly expansion is run for each calendar year of survey data to produce catch and effort estimates for the pelagic fishery to avoid overestimating seasonal pelagic species. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for all pelagic species and the PMUS separately are summed across all methods to obtain the numbers plotted above.

Figure 1b. Guam Annual Estimated Total Landings: Total, Non-Charter, and Charter Pelagics

Interpretation: Non-charter trolling trips have always accounted for the bulk of the pelagic catch, although charter boats, which make up less than 5% of the troll fleet, account for a high proportion of trolling effort and catch. Prior to 1988, non-charter boats accounted for over 90% of the troll catch. In 1988, this percentage decreased due to an increase in charter boat activity catering specifically to Asian visitors. Beginning in 1996 however, a downturn in Japan's economy caused a significant decrease in charter trips and subsequent landings. No such trend is observed for non-charters. In 2011, total pelagic landings decreased 19%, non-charter landings decreased 16.8%, while charter landings decreased 58.6%. Non-charter boats landed 95.7% of all pelagics in 2011.

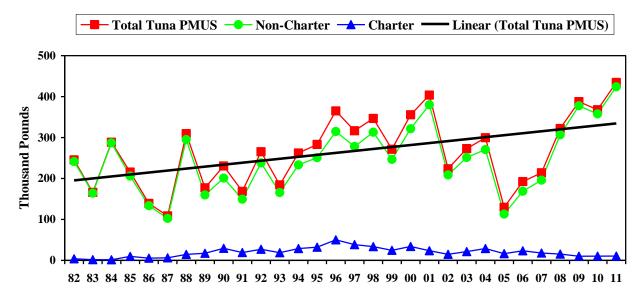

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel survey data.

Calculation: A 365-day (366 days during leap years) quarterly expansion is run for each calendar year of survey data to produce catch and effort estimates for trolling. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for all pelagic species and the PMUS separately are summed across all methods to obtain the numbers plotted above.

Figure 1c. Guam Annual Estimated Tuna PMUS Landings: Total, Non-Charter, and Charter

Interpretation: The general trend of the estimated total tuna landings shows an increasing trend between 1987 and 2001. Non-charter boats account for the bulk of the total tuna catch, up to 95% in the 1980's. This decreased when charter boat activity began increased from the late 1980's until the mid 1990's. In 2011, 97% of tuna were caught by non-charter boats. In 2011, total tuna and non-charter landings increased by 18% and 19% respectively. Charter tuna landings increased by 2% from 2010 totals. The 2011 estimated tuna PMUS landings were the highest in the time series, and 64% higher than the 30 year average.

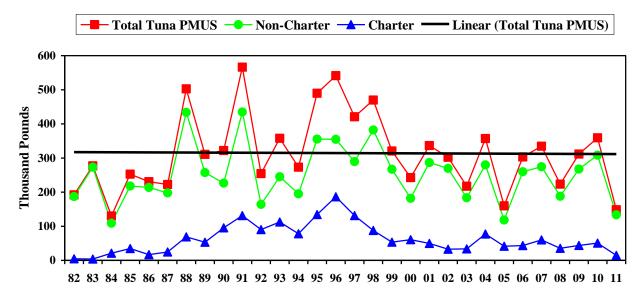

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program, expanded with the assistance of NMFS.

Calculation: A 365-day (366 days during leap years) quarterly expansion is run for each calendar year of survey data to produce catch and effort estimates for trolling. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for all pelagic species and the PMUS separately are summed across all methods to obtain the numbers plotted above.

Figure 1d. Guam Annual Estimated Landings: Total, Non-Charter, and Charter Non-Tuna PMUS

Interpretation: The estimated total non-tuna PMUS landings showed a general increase between 1984 and 1996, corresponding with an increase in boats entering the fishery. Non-charter trolling trips accounts for the bulk of the other PMUS catch. Up until the mid-1980's, non-charter boats accounted for up to 90% of the non-PMUS species. This percentage began decreasing in the late 1980's when charter fishing activity began increasing, associated with an increase in tourism. Charter PMUS harvest began gradually decreasing after 1996. Non-charter PMUS landings also began decreasing after 1996, but exhibit year to year fluctuations. In 2011, total non-tuna PMUS and non-charter non-tuna PMUS decreased 58% and 57% respectively when compared with 2010. Charter non-tuna PMUS decreased 71%. These decreased levels may be due to the biology of non-tuna PMUS species, primarily mahi mahi. Additionally, poor weather conditions limited the number of fishing days in 2011. Non-charter boats accounted for 90% of non-tuna PMUS catch in 2011.

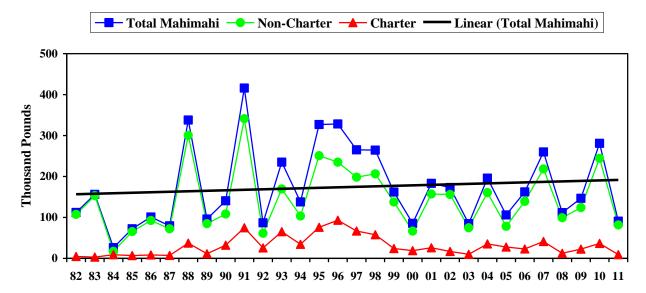

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program, expanded with the assistance of NMFS.

Calculation: A 365-day (366 days during leap years) expansion is run for each calendar year of survey data to produce catch and effort estimates for each fishing method surveyed. Percent species composition is calculated by weight for the sampled catch for each method to produce catch estimates for each species for the expanded period. The annual catch for all pelagic species and the PMUS separately are summed across all methods to obtain the numbers plotted above.

Figure 2a. Guam Annual Estimated Total Mahimahi Landings: All Mahimahi, Mahimahi NC, and Mahimahi C

Interpretations: Historically, mahimahi catches have fluctuated wildly, with a good year followed by one or two down years. Catch peaked in 1996, and has been lower since, although still demonstrating the cyclical nature. Non-charter trips account for the bulk of the mahimahi catch, with charter activity harvesting proportionally more beginning in the late 1980's as tourist arrivals to Guam increased. A drop in charter catch corresponds to decreasing tourist arrivals in the late 1990's. In 2011, mahimahi landings decreased, with total and non-charter landings increasing 67% and 67%, respectively. Charter landings decreased by 75%. All three categories are well below the 30 year average.

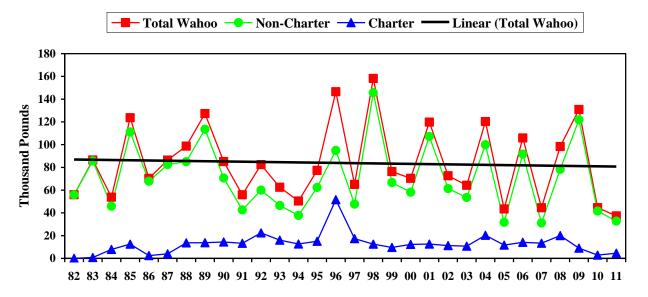

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS.

Calculation: Totals by species are summed across all fishing methods as described in Figures 1a to 1d.

Figure 2b. Guam Annual Estimated Total Wahoo Landings: All Wahoo, Wahoo NC, and Wahoo

Interpretations: The wide fluctuations in wahoo landings are probably due to the high variability in the year-to-year abundance and availability of the stocks. Until 1987, non-charter landings accounted for over 95% of the total catch. In 1988, this percentage decreased due to an increase in charter boat activity. In 1996, wahoo charter landings peaked, accounting for 35% of the total catch. In 2011, total and non-charter, harvest of wahoo decreased 16.2% and 21.3%, respectively, while charter wahoo catch increased by 57% from 2010. Non-charter boats harvested 88% of the total wahoo harvest. The total wahoo catch was 55% below the 30 year average, and is the lowest total in the time series.

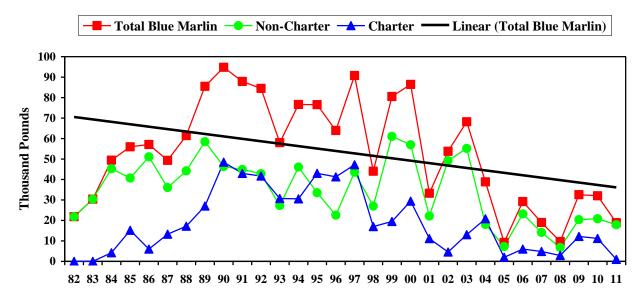

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS.

Calculation: Totals by species are summed across all fishing methods as described in Figures 1a to 1d.

Figure 3a. Guam Annual Estimated Total Blue Marlin Landings: All Blue Marlin, Blue Marlin NC, and Blue Marlin C

Interpretations: During the 1980's, non-charter boats accounted for the bulk of the blue marlin catch. In the early 1990's, charters share of the marlin catch began to increase, peaking at 64% in 1996. The increases were due to an increase in charter boat activity and the active targeting of blue marlin by charter boats during the summer months. The decrease in charter landings after 1997 corresponded to the decrease in tourist charter trips. In 2011, all categories of marlin catch decreased. Total catch was down 41%, non- charter catch was down 14%, and charter catch was down 91% Charter blue marlin catch accounted for 5% of the total blue marlin harvest. Blue marlin landings were below the 30 year average in all categories. The charter total is the lowest in the time series.

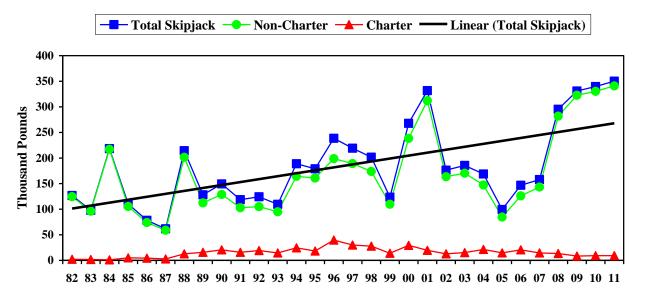

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS.

Calculation: Totals by species are summed across all fishing methods as described in Figures 1a to 1d.

Figure 4a. Guam Annual Estimated Total Skipjack Landings: All Skipjack, Skipjack NC, and Skipjack C

Interpretations: Skipjack tuna catch has fluctuated over the reporting period, reaching a high point in 2001. A drop in skipjack tuna during 2002 may be due to direct hits by two super typhoons. The reason for the high numbers of 2001 is not clear. It could have to do with the biology of the species. An increasing catch in skipjack tuna since 2007 reflects an increase in small boats targeting this species. These boats are primarily crewed by Micronesian fishermen.

Total skipjack tuna landings and non-charter landings increased in 2011 by 3% and 3% respectively, while charter landings decreased by .3%. Total catch is 89.7% above the 30-year average, and is the highest total in the time series.

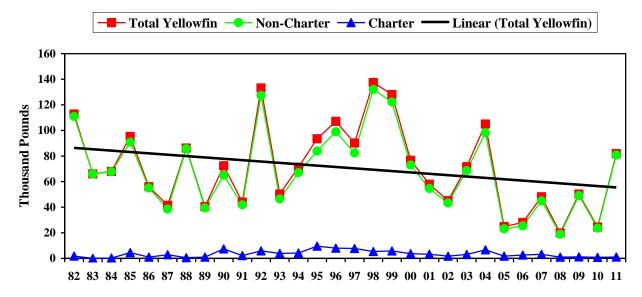

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS.

Calculation: Totals by species are summed across all fishing methods as described in Figures 1a to 1d.

Figure 4b. Guam Annual Estimated Total Yellowfin Landings: All Yellowfin, Yellowfin NC, and Yellowfin C

Interpretations: The overall yellowfin landings show wide fluctuations during the 30-year time series, although the total and non-charter estimated landings showed a significant decrease from 1998 to 2002. Charter landings of yellowfin tuna peaked in 1985, 1990, and 1995, and then showed a general decrease until 2002. Yellowfin tuna catch was up significantly in 2011, with total catch, non-charter catch, and charter catch up 234%, 241%, and 24.7%, respectively. Non-charter boats harvested 98.7% of the total yearly catch of yellowfin. Total catch and non-charter catch are above their 30-year averages, while the charter total is well below the average for the time series. An increase in the number of vessels targeting small tuna may be the source of the increased catch totals.

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS.

Calculation: Totals by species are summed across all fishing methods for all years except 1992-93 as described in Figure 1.

Figure 5. Guam Annual Estimated Commercial Landings:
All Pelagics, Tuna PMUS, and Non-tuna PMUS

Total Pelagics — Tuna PMUS — Non-Tuna PMUS — Linear (Total Pelagics)

Interpretations: Commercial pelagic fishery landings have shown a general increase for the first 20 years in the 30-year time series. In 2002, the estimated commercial landings decreased overall by 17%, with a 15% decrease for tuna landings and a 20% decrease for landings of other PMUS, possibly due to direct hits by two super typhoons, resulting in boat damage, lack of tourist for the commercial charter boats, and unavailability of ice for fishermen. Total commercial catch

decreased 36% from 2010. Total commercial catch is 44% below the 30 year average.

Source: The WPACFIN-sponsored commercial landings system.

500

400

300

200

100

0

Thousand Pounds

Calculation: Total commercial landings were estimated by summing the weight fields in the commercial landings database from the principle fish wholesalers on Guam, and then multiplying by an estimated percent coverage expansion factor. The annual expansion factor was subjectively created based on as much information as possible depending on the year, including: an analysis of the "disposition of catch" data available from the DAWR offshore creel survey; an evaluation of the fishermen in the fishery and their entry/exit patterns; general "dock side" knowledge of the fishery and the status of the marketing conditions and structure; the overall number of records in the data base; and a certain measure of best guesses.

Figure 6. Guam Estimated Number of Trolling Boats

Interpretations: Since 1982, the general trend on Guam has been an increase in the number of boats participating in the pelagic fishery, especially since the addition of two marinas to the offshore sampling program. There appears to be a general increase in the number of small boats participating in Guam's pelagic fishery, while the number of charter vessels has remained fairly constant for several years. In 2011, the number of boats was 454, an increase of 5% from 2010.

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS.

Calculation: Since only a fraction of the days of the year are sampled, it is not possible to know the exact number of boats participating in the fishery. The 2011 trolling boat log was converted and processed through a boat estimator model 1,000 times.

Figure 7a. Guam Estimated Number of Trolling Trips

Interpretations: Non-charter and charter troll trips generally increased for the first 15 years of the 26-year time series. The number of troll trips began to decline in 1999, due to a number of factors including a continuing economic recession on the island, a decline in Asian visitors for charter boats, and an increase in cost to maintain, repair, and fuel boats for the average fishermen compared with fish caught for sale to make up for expenses. In 2011, the total number of troll trips decreased by 23.8%, and the number of non-charter trips decreased by 21%. The number of charter trips decreased by 39%. The decrease in non-charter trips may be attributed to an increase in gas prices, as well as an exceptionally high number of bad weather days during 2011. Total trips are 14% below the 30 year average.

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files.

Calculation: The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. These plots are of the estimated number of trips for the trolling method as taken directly from creel survey expansion system printouts.

Figure 7b. Guam Estimated Number of Trolling Hours

Interpretations: Trolling hours for non-charters and charters have generally increased over the past 20 years. Beginning in 1996, charter troll hours began to decrease. This corresponded to a downturn in Asian economies, which resulted in fewer charter trolling hours. After 2001, charter activity dropped off dramatically. Tourism was also down, due to the 9/11 attacks, the SARS scare, and two typhoons striking Guam in 2002. Since 2005, the number of hours trolling has generally been increasing. In 2011, however, total and non-charter totals decreased by 16% and 13%, respectively, while charter hours decreased by 42%. The decrease in hours trolling may be attributed higher gas prices and a high number of bad weather days in 2011. Total hours trolling is 13% below the 30-year average.

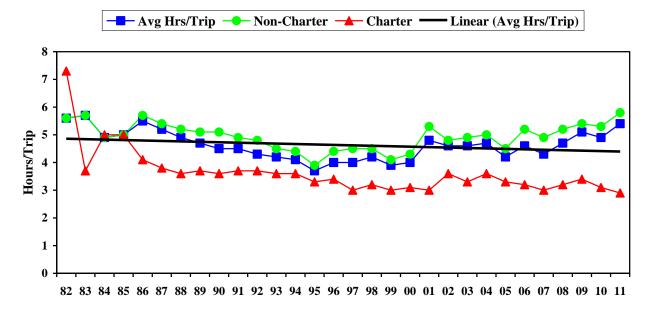

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files.

Calculation: The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. These plots are of the estimated boat hours spent fishing for the trolling method as taken directly from creel survey expansion system printouts.

Figure 7c. Guam Estimated Number of Trip Length

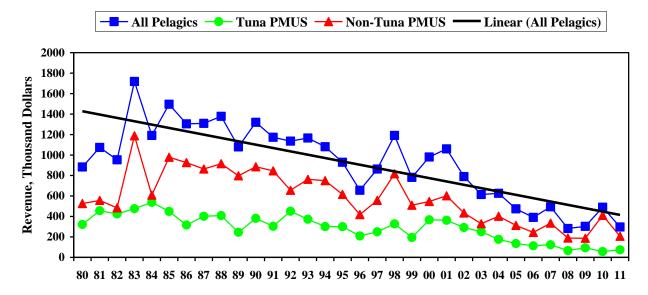

Interpretations: The overall average trolling trip decreased slightly from 2009. The redeployment of fish aggregating devices (FADs) still provide charter boats and non-charter fishermen with a prescribed route for trolling activity, although many boats have been observed to be making longer trips to the banks located north and south of Guam. Overall trolling trip length appears to have remained fairly constant throughout the 30-year time series. In 2011, total and non-charter categories showed an increase, with the average number of hours per trip up 10%. This is 17% higher than the 30 year average. **Source:** The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files.

Calculation: The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. These plots are of the estimated boat hours spent fishing and number of trips for the trolling method, as taken directly from creel survey, expansion system printouts.

Figure 8. Guam Annual Estimated Inflation-Adjusted Commercial Revenues: All Pelagics, Tuna PMUS, and Non-Tuna PMUS

Interpretations: The estimated inflation-adjusted commercial revenues for 2009 increased 7% for total, 42% for tuna PMUS, and decreased 1.4% for non-tuna PMUS. Overall, commercial revenues have shown a gradual decrease since the early 1980's. A large drop occurring after 2002 can partly be attributed to two typhoons striking Guam, as well as a change in government policy (see introduction). This trend somewhat continued in 2011, with all three adjusted revenue categories well below the 30-year averages.

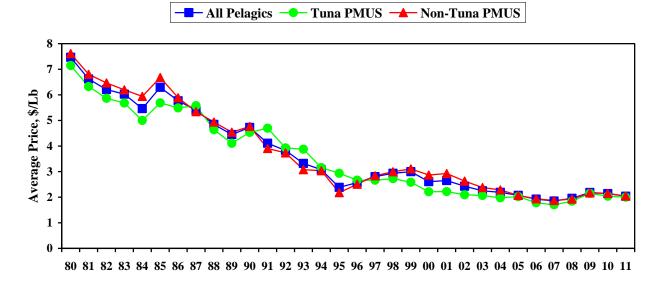

Source: The WPACFIN-sponsored commercial landings system.

Calculation: Commercial revenues were estimated by summing the revenue fields in the commercial landings database from the principle fish wholesalers on Guam, and then multiplying by the same percent coverage expansion factor, as in figure 5. Inflation-adjusted total revenue per trip is derived from the Guam Annual Consumer Price Index (CPI).

Inflation-Adjusted Commercial Revenues (\$) from Commercial Receipt Books (data for Figure 8)

Figure 9. Guam Annual Estimated Inflation-Adjusted Average Price of: All Pelagics, Tuna PMUS, and Non-tuna PMUS

Interpretations: The inflation-adjusted price of tuna and other non-tuna PMUS has shown a dramatic decline since data on the pelagic fishery was first collected in 1980. In 2007, the trend started to change slightly. In 2011, prices were virtually unchanged, with the adjusted price for all pelagics decreasing 4.7%, 2% for tuna PMUS, and 5% for non-tuna PMUS species. All three categories are well below their 30 year averages. Locally caught pelagic fish continues to have to compete with cheaper pelagic fish caught by longliners. These are value-added products sold at several supermarkets and roadside vendors.

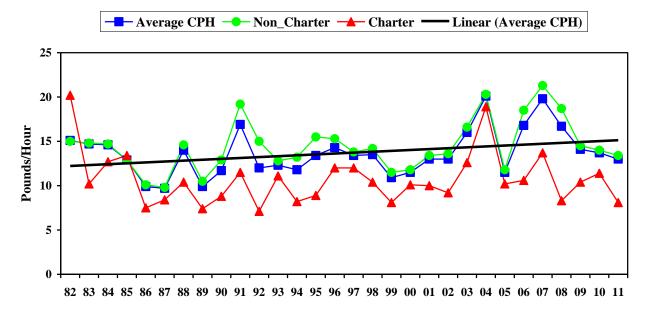

Source: The WPACFIN-sponsored commercial landings system.

Calculation: The average price of the Tunas and other PMUS groups are calculated by dividing the total revenue for each by the sold weight. The inflation adjustment is made by using the Consumer Price Index (CPI) for Guam and establishing the current year figure as the base from which to calculate expansion factors for all previous years (e.g., divide the current year CPI by the CPI of any given year), and then multiplying that factor by the unadjusted average price for the given year.

Inflation-Adjusted Average Price (\$/Pounds) from Commercial Receipt Books (data for Figure 9)

Figure 10a. Guam Trolling Catch Rates (Lbs/Hr):

Interpretations: The fluctuations in CPUE are probably due to variability in the year-to-year abundance and availability of the stocks. However, since it is not possible to allocate species-specific effort, effort used to target other species can also result in artificially high or low catch rates for a given species. This is especially true with charter boats targeting blue marlin during the summer months. In 2011, total overall, and non-charter catch rates decreased 5.1% and 4.3%, respectively. Charter catch rates decreased by 29%. Charter catch rates have generally been lower than catch rates of non-charter boats, probably due to their shorter fishing time, and non-charter boats beginning earlier in the morning and ending as late as early evening.

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files.

Calculation: The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method. This plot and table of catch per unit of effort (CPUE) are based on the total annual landings of all troll catch, divided by the total number of hours spent fishing (gear in use).

Figure 11a. Guam Trolling Catch Rates (Lbs/Hr): Skipjack

Interpretations: The wide fluctuations in CPUE for skipjack tuna are probably due to the high variability in the year-to-year abundance and availability of the stocks, although skipjack tuna is caught year round. However, it is not possible to allocate species-specific effort, since effort used to target other species can result in an artificially high or low catch rate for a given species. In 2011, the catch rates for total and non-charter increased by 23.8% and 19.1%, respectively. Charter rates increased 76.5% in 2011. Total CPUE was 81% above the 30-year average.

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS.

Calculation: The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. This plot and table of catch per unit of effort (CPUE) are based on the total annual landings of skipjack divided by the total number of hours spent fishing (gear in use).

Figure 11c. Guam Trolling Catch Rates (Lbs/Hr): Blue Marlin

Interpretations: The wide fluctuations in CPUE are probably due to the high variability in the year-to-year abundance and availability of the stocks. Since it is not possible to allocate speciesspecific effort, effort used to target other species can also result in an artificially high or low catch rate for a given species. The 2011 blue marlin non charter catch rates were virtually unchanged from 2010. Total CPUE was down 33%, while charter CPUE was down 86% Total catch CPUE is 67% below the 30 year average

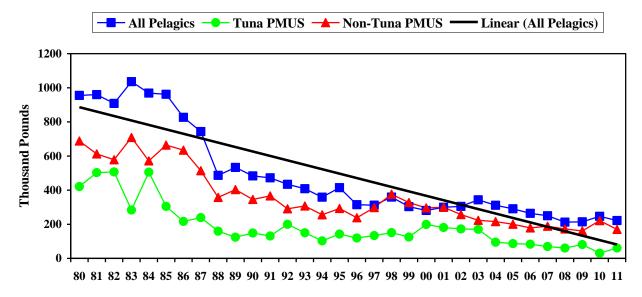

Source: The Division of Aquatic and Wildlife Resources (DAWR) offshore creel sampling program and its associated computerized data expansion system files, expanded with the assistance of NMFS.

Calculation: The data expansion system is run on a calendar year's worth of survey data to produce catch and effort estimates for each fishing method surveyed. This plot and table of catch per unit of effort (CPUE) are based on the total annual landings of marlin divided by the total number of hours spent fishing (gear in use).

Figure 12. Guam Annual Estimated Inflation-Adjusted Revenue per Trolling Trip:
All Pelagics, Tuna PMUS, and Non-tuna PMUS

Interpretation: There has been a general decrease from 1980 in the adjusted revenues per trolling trip for all pelagics, tunas and other PMUS, although the revenue values have remained fairly constant for past 9 years. In 2011, the adjusted revenue per trip increased for all pelagics by 10%. Tuna PMUS revenues increased by 98%, and non-tuna PMUS increased by 23%. Despite continual declines in revenues, trolling effort still occurs since most charter and non-charter trolling boats do not rely on selling fish caught as their primary source of income and a reliable market exists for members of the local fishermen's cooperative which provides additional income.

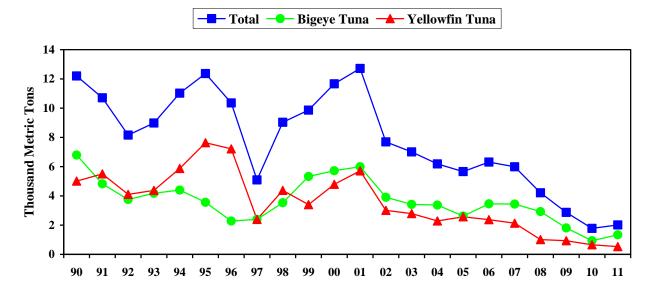

Source: The WPacFIN-sponsored commercial landings system.

Calculation: The average revenue per trip was calculated by summing the revenue of all species sold then dividing by the number of trips, and summing the revenue of tunas and other PMUS sold, and then dividing each by the number of trips, respectively, for any trip, which landed PMUS. Adjusted revenue per trip was derived from the Guam Annual Consumer Price Index (CPI).

Figure 13. Guam Foreign Longline Transshipment Landings Longliners Fishing Outside the Guam EEZ

Interpretation: Annual landings from a primarily foreign longline fishing fleet have ranged from a low of 2874 metric tons in 2009 to a high of 12,627 metric tons in 2001. These vessels fish primarily outside Guam's EEZ, but transship their catch through Guam. The dramatic drop observed in 1997 was due to a large number of foreign fishing boats leaving the western Pacific that year for several reasons, including availability of fish stocks. In 2011 total longline landings increased 13%, with bigeye landings increasing 43%, and yellowfin landings decreasing 19%. 2011 yellowfin totals were the lowest in the 22 year data set, and total catch was 74% below the 22 year average. The lower numbers may be due to a reduction in the number of agents reporting sales, and vessels relocating to other regions of the Pacific.

Source: The Bureau of Statistics and Plans.

Calculation: Pre-1990 data was extracted directly from transshipment agents' files. Beginning in 1990, a mandatory data submission program was implemented.

2011	0	1	1	7100	.00014	1	496	.002

^{*&}quot;percent bycatch" represents the number of pieces that were discarded compared to the total number of fish caught trolling. The bycatch information is from unexpanded data, taken only from actual interviews that reported bycatch.

Interpretation: Bycatch information was recorded beginning in 2000 as a requirement of the pelagic FMP. Historically, most fish that is landed by fishermen is kept regardless of size and species. Bycatch for this fishery are sharks, shark-bitten pelagics, small pelagics, or other pelagic species. In 2010, bycatch was not encountered by Fisheries staff when interviewing trollers.

Source: The DAWR creel survey data for boat based methods.

Calculations: Bycatch is obtained directly from trolling interviews where bycatch was voluntarily reported. The number of bycatch reported is from unexpanded data.

Bycatch Summary

Species Name	Number Released			Number Caught	Bycatch(%)
	Number Alive	Released Dead/Injured	Both
